A Chunk-based n-gram English to Thai Transliteration

Wirote Aroonmanakun, Non-member

ABSTRACT

In this study, a chunk-based n-gram model is proposed for English to Thai transliteration. The model is compared with three other models: table lookup model, decision tree model, and statistical model. The chunk-based n-gram model achieves 67% word accuracy, which is higher than the accuracy of other models. Performances of all models are slightly increased when an English grapheme to phoneme is included in the system. However, the accuracy of the system does not suffice to be a public transliteration tool. The low accuracy of the system is caused by the poor performance of the English grapheme to phoneme module and the inconsistency of pronunciation in the training data. Some suggestions are provided for further improvement.

Keywords: English-Thai Transliteration

1. INTRODUCTION

English to Thai transliteration is a way to write English words in the Thai alphabet. While English has 26 characters for 24 consonant and 20 vowel sounds, Thai has 44 characters for 21 consonant sounds, and 19 characters (including 3 consonant characters) for 24 vowel sounds (including 6 diphthongs), and 4 characters for tone markers. It is quite usual for an English word to be transliterated in Thai differently. For example, the word “internet” are written as อินเทอร์เน็ต, อินเทอร์เน็ต, อินเทอร์เน็ต, อินเทอร์เน็ต, อินเทอร์เน็ต, or อินเทอร์เน็ต. To standardize the transliteration, the Thai Royal Institute issued regulations of English-Thai transliteration in 1982. Nevertheless, many people tend to transliterate English words on their own rather than adhering to the regulations. But if an English-Thai transliteration software that conforms to the Royal Institute’s guideline is available to the public, the diversity should be low. In this study, we aim to develop such a system. A corpus of transliterated words is created by collecting English and Thai word pairs from books published by the Royal Institute. A total of 8,181 word pairs are used in this study. In each word pair, Thai characters are aligned with English characters. Alignments between English and Thai characters are first assigned by a program and then manually corrected. It is possible that more than one character in English or Thai is aligned, e.g. ‘th’-‘ถ’, ‘ia’-‘ิ’. Examples of aligned characters between word pairs are shown below. These data will be used for training the transliteration systems.

This paper first reviews previous models of transliteration systems. Table lookup, decision tree, and statistical models are briefly discussed. Then, a new approach of chunk-based n-gram model is described in section 3. The results when using each model are reported and compared in section 4. Since knowing English pronunciation is usually useful for transliteration, all the models are re-tested by applying a module of English grapheme to phoneme. The new results are reported in section 5. Though the chunk-based n-gram model performs better than other models, the accuracy is not high enough to be used as a tool for the public. At the end, we will review and discuss the problems for further improvements.

2. PREVIOUS RESEARCH

Since transliteration is basically a process of transforming one writing system into another writing system, approaches used in any transliteration systems as well as those used in grapheme to phoneme systems are relevant. In this study, three different approaches, namely table lookup, decision trees, and statistical model, are reviewed and implemented in this study.
2.1 Table Lookup Model

The model is based on Bosch and Daelemans’ grapheme-to-phoneme conversion model [2]. It is used for transcribing English, French, and Dutch. Conversion of characters to phonemes is done by applying conversion rules, which are extracted from a training corpus. But in this study, the conversion rules are used for converting English characters to Thai characters. Rules are stored in a lookup table as a mapping from English characters to Thai characters, which is determined by the left and right contexts of the English characters. By using a training corpus composed of word pairs aligned between characters of the two languages, if the target language character can be uniquely determined from the source language character within its minimal context, the conversion rule will be stored in a lookup table. But when the same context does not uniquely determine the target language character, conversion are done by default mapping by selecting the most occurring target character in that context. In this study, lookup tables of various context sizes are implemented: 0-0, 0-1, 1-1, 1-2, 2-2, 2-3, 3-3, 3-4, 4-4, 4-5, and 5-5. (The two digits indicate the number of characters on the left and right contexts) Default mapping of 0-0, 0-1, 1-1, and 2-2 contexts are used when no lookup table is applicable.

2.2 Decision Tree Model

Decision tree model converts symbols from one language to another by applying rules that are in the form of decision trees. The input is checked against a sequence of conditions defined as a tree diagram. The output when the sequence of conditions is matched is stated on the leaf node of the tree. Kang and Choi [3] use this model for Korean-English transliteration system. Decision trees are created by applying a well-known machine learning technique, ID3. This method is often applied to many NLP systems, such as Thai grapheme to phoneme [4], word sense disambiguation [5]. In this study, Lenzo’s Perl program [6] for English grapheme to phoneme is modified to create decision trees for English-Thai transliteration. The maximum depth of trees (the number of conditions) is set to 7. The left and right contexts (the conditions) are set to 3 characters.

2.3 Statistical Model

The third model is a statistical model, which is often used in transliteration research, such as Japanese-English back-transliteration [7], English-Arabic transliteration [8], English-Korean transliteration [9], English/Japanese transliteration [10] [11], English-Korean transliteration [12], etc. Transliteration problem is viewed as a probabilistic model. In this study, English-Thai transliteration can be viewed in a similar way as follows:

\[
\arg \max_{T_w} P(T_w | E_w) = \arg \max_{T_w} \frac{P(T_w) \cdot P(E_w | T_w)}{P(E_w)} = \arg \max_{T_w} P(T_w) \cdot P(E_w | T_w)
\]

\[
P(T_w) = \prod_{n=1}^{2} P(T_{c_i}, T_{c_2}, ..., T_{c_n}) = \prod_{i=1}^{n} P(T_{c_i} | T_{c_i-1})
\]

\[
P(E_w | T_w) = \prod_{i=1}^{n} P(E_{c_i} | T_{c_i})
\]

In this model, transliteration is viewed as a probabilistic model of transliteration pairs between English and Thai words. The optimal Thai transliterated word when given an English word is the Thai word that yields the greatest probability P(Tw | Ew), which can be calculated as the product of two probabilities, P(Tw) and P(Ew | Tw). P(Tw) can be estimated by using a trigram model of Thai characters, while P(Ew | Tw) can be estimated by using the conditional probability of alignments between English and Thai characters.

Another variation of statistical model is based on Haizhou et al.’s joint source-channel model [13]. In this model, both source and target characters are taking into consideration.

\[
\arg \max_{T} P(T | E) = \arg \max_{T} \frac{P(T, E)}{P(E)} = \arg \max_{T} \frac{P(T, E)}{P(E)} = \arg \max_{T, E} \prod_{i=1}^{n} P(T_{c_i} | T_{c_i-1})
\]

The optimal transliterated Thai word (T) for a given English word (E) is the one that yields the greatest probability P(T | E), which can be calculated from the probability of alignments between Thai and English characters. It then can be estimated as a trigram model of the alignments.

3. CHUNK-BASED N-GRAM MODEL

The model proposed in this study is a chunk-based n-gram model. It is based on Kang and Kim’s view of phoneme chunks [9] and Haizhou et al.’s joint source-channel model [13]. In this chunk-based model, alignment between English and Thai characters can have various lengths. For example, for the word pair “locarno” ลำคราโน, beside
Like other statistical models, transliteration here is viewed as a probabilistic model of transliteration pairs between Thai and English. But in this model, the units of transliteration pair can be a chunk of characters. Probabilities of a sequence of transliteration pairs are estimated by a trigram model in this study. The sequence with the greatest probability will be selected as the optimal solution.

$$\text{arg max}_T P(T|E) = \text{arg max}_T \frac{P(T,E)}{P(E)} = \text{arg max}_T P(T,E)$$

$$= \text{arg max}_T P(t_i, t_j, c_i, c_j, \ldots)$$

$$= \text{arg max}_T P(<t_i, c_i, t_j, c_j, \ldots> <t_i, c_i, t_j, c_j, \ldots> \ldots <t_i, c_i, t_j, c_j, \ldots>)$$

$$= \text{arg max}_T \prod_{t=1}^{n} P(<t_i, c_i, t_j, c_j, \ldots>)$$

$$(c_t, \text{and } c_e \text{are a chunk of Thai and English characters})$$

For example, when transliterating a word 'unitarian', there could be many possible sequences of transliteration pairs as follows:

- <unita,ยูนิทเ>,<r,ร>,<ian,ียน>
- <unita,ยูนิทเ>,<r,ร>,<i,ไ>,<an,อื่น>
- <unitar,ยูนิทเ>,<t,ต>,<a,อา>,<rian,ียน>
- <uni,ยูน>,<t,ต>,<a,อา>,<rian,ียน>
- ...

The probability of each sequence is calculated based on trigram statistics of all transliteration pairs in the training data. Using this model, it is likely that a sequence with fewer chunks will have a greater probability than a sequence with longer chunks and chunks with high occurrences will have a greater probability than chunks with low occurrences.

4. EXPERIMENTS

The corpus of 8,181 English-Thai pairs is divided into five data sets. One data set is used as the test data while the other four data sets are used as the training data. To eliminate the bias from data test, each data set will be used as the test data for all models. Thus, all models will be tested five times. The results from the five tests will be averaged as the performance of each model. This indicates the performance on unseen data. Each model is also tested for seen data (All data sets are used for both training and testing).

Performance is measured in two ways: word accuracy (W.A.) and character accuracy (C.A.) [9]. W.A. is counted from the exact match of the generated words and the correct word. C.A. is calculated on the basis of edit distance between the two words. C.A. = (L – (i + d + s)) / L, where L is the length of a word, and i, d, s is the number of insertion, deletion, and substitution that are needed to change the result to match the target word. The results from each model, table lookup model (TB), decision tree model (DT), n-gram model (N-gram), joint-source channel model (Joint), and chunk-based n-gram model (Chunk), are presented in Table 1.

<table>
<thead>
<tr>
<th>Table 1: Result of English-to-Thai transliteration</th>

<tr>
<td>TB</td>
</tr>
<tr>
<td>DT</td>
</tr>
<tr>
<td>N-gram</td>
</tr>
<tr>
<td>Joint</td>
</tr>
<tr>
<td>Chunk</td>
</tr>
</tbody>
</table>

It can be seen that the chunk-based n-gram model performs better than other models for both unseen and seen data. For unseen words, the accuracy at the word level is 67.4%, and the accuracy at the character level is 88.9%. For seen words, word accuracy of the chunk-based n-gram is 99.8% and character accuracy is 99.9%.

5. ADDING E2P MODULE

Knowing how the word is pronounced is usually useful for transliteration from English to Thai. In fact, to transliterate an English vowel correctly, it is necessary to know how it is pronounced. For example, one vowel form 'i' can be transliterated to three Thai vowel forms, ไ, ี, ิ depending on the pronunciation of that vowel. Therefore, the systems are tested again by adding a module of English grapheme to phoneme (E2P) as a part of the system. But only three models, TB, DT, and Chunk-based, are tested at this time. The systems are implemented by considering both English characters and phonemes in this new test. E2P module is created by applying lookup tables, which are generated from a CMU pronunciation dictionary. The accuracy of the E2P is measured at 56.7% for W.A., and 90.8% for C.A. The new result of the systems when including E2P is shown in Table 2.
Table 2: Result when E2P is included

<table>
<thead>

<tbody>
<tr>
<td></td>
<td>W.A</td>
<td>C.A</td>
<td>W.A</td>
</tr>
<tr>
<td>TB</td>
<td>65.3%</td>
<td>88.4%</td>
<td>99.7%</td>
</tr>
<tr>
<td>DT</td>
<td>64.4%</td>
<td>88.0%</td>
<td>97.5%</td>
</tr>
<tr>
<td>Chunk</td>
<td>68.1%</td>
<td>88.7%</td>
<td>99.8%</td>
</tr>
</tbody>
</table>

It can be seen that all models perform a bit better when English G2P is included. And the chunk-based model is still the best model in this study.

6. DISCUSSIONS

Although the chunk-based n-gram model performs better than other models, the accuracy of the system is still not high enough for using as a transliteration tool for the public. To improve the performance, error analysis is needed to understand why some generated words do not match the correct words.

Two factors are likely the causes of low accuracy: accuracy of E2P and different accents of pronunciation. The accuracy of E2P module developed in this study is not really high. It yields only 56.7% for word accuracy and 90.8% for phoneme accuracy. Creating a good E2P module is difficult. Black et al. [14] also reported the accuracy of their E2P system at 57.80% for word accuracy and 91.99 for phoneme accuracy when using CMU pronunciation dictionary in their tests, while the accuracy when using Oxford Advanced Learners Dictionary of Contemporary English is higher (74.56%). Black et al. explained that the difference lied on the fact that CMU dictionary includes a lot more proper names. According to Llitjós [15], E2P systems that produce high accurate results are those that are dictionary-based. Transliteration rules are used only when the input word is not listed in the dictionary. Therefore, to improve E2P performance, a pronunciation dictionary should be used directly. However, in English-Thai transliteration, many input words are proper names. It is unlikely to have all names and their pronunciations listed in the dictionary. It is still necessary to create a good E2P module that is not a dictionary-based.

Different accents of pronunciation could also be another cause of low accuracy in this study. Since transliteration is partly based on the pronunciation of English words and the same word can be pronounced with different accents, i.e. British or American pronunciations, the transliterated words then could be written differently. For example, the word “Leonard” is found transliterated in the Royal Institute’s books as เลนารด, เลนเนิรด, and เลียวนารด. Although, in this case, only one form that, we think, is most conformed to the guideline is stored in the corpus, it does not exclude the possibility of different accents entailed in different words. This inconsistency of the training data could result in inefficiency of transliteration rules.

In addition, when the generated words do not exactly match the correct words, it is possible that the generated word is another form of acceptable transliterations. For example, the word “ballast” is transliterated by the chunk-based system as บัล ลาสต, while the correct word is แบลลาสต. The difference of vowel form in this case is resulted from different accents of pronunciation. In this example, the generated word is considered an acceptable result. Therefore, the results are rechecked manually whether they are acceptable transliteration. Using this acceptable criterion, it is found that the accuracy of the chunk-based model gains up to 84%.

7. CONCLUSION

Although the chunk-based model performs better than other systems, 68-84% W.A. is not a satisfying result. To be released as an English-Thai transliteration tool for the public, the program should have high accuracy up to 98%. The system has to be improved by employing a good E2P. And it might be necessary to manually clean up the training data to make English pronunciation in the transliterated words consistent with one particular accent. Beside, the chunk-based model uses more resources than other models. It is needed to be improved in terms of processing speed. In addition, to verify that the chunk-based n-gram model is better than other models, a similar test should be performed on transliteration of other languages.
